Abstract

The article presents data on the change in the cellular composition of the lymph nodes of the white rats, males of reproductive age, who received intramuscular opioid analgesics – nalbuphine every day for six weeks. The weekly dose of nalbuphine was gradually increased, creating a model of physical opioid dependence according to the patent of Ukraine No. 76564 U. All experimental animals were divided into 8 groups.

Morphometric method was used to determine the relative number of cells of the lymphoid series – small, medium and large lymphocytes, blasts and plasmocytes in the cloak zone and the embryonic center of the secondary lymphoid nodes and brain strands of the lymph nodes. Morphometric studies were performed using a system of visual analysis of histological preparations.
It was established that nalbuphine in the lymph nodes causes reactive and destructive changes: the number of large lymphocytes increases in all structural components of the lymph node with a maximum after 4 weeks, respectively, the relative number of small lymphocytes decreases in the nucleus centers and brain tracts, the relative number of plasmocytes in the brain strains increases sharply. In all structural components of the lymph nodes hemocapillaries and venules are dilated and full-blooded, around vascular edema and partial damage to the walls of the microvessels.

One week after the discontinuation of nalbuphine, the relative number of lymphoid cells in the structural components of the lymph nodes does not return to the indicators of intact animals, no reversible changes are noted.

animals daily for six weeks in the right intramuscular region of the mitochondria. All experimental animals were divided into 8 groups and the weekly dose of the injection preparation was increased in progressive order (Table 1) according to the patent number 76564 U "Method for the simulation of physical opioid dependence in rats" [20]. The studies were also carried out 1 week after the discontinuation of nalbuphine (group 8).

The research was conducted on the basis of the Lviv National Medical University named after DanyloHalytsky, in accordance with the agreement dated November 18, 2013 on cooperation between the department of normal anatomy of the Lviv National Medical University named after DanyloHalytsky and the Department of human anatomy and histology of the Faculty of medicine of Uzhgorod National University during 2014–2017.

Control was provided with 12 rats, which, in place of nalbuphine, were similarly injected with a 0.9 % solution of sodium chloride.

Experiments on animals were conducted in accordance with the provisions of “The European convention for the protection of vertebrate animals used for experimental and other scientific purposes” (Strasbourg, 1986), Council Directives 86/609/EEC (1986), Law of Ukraine No. 3447-I “On protection of animals from cruel treatment “,” General ethical principles of experiments on animals “, adopted by the National congress of Ukraine on bioethics (2001).

The animals were kept in vivarium in accordance with generally accepted rules, on a standard diet. For fetching of the studied organs – the iliac lymph nodes – the experimental animals were extracted from the experiment by anesthetizing the with intraperitoneal anesthesia using thiopental natrium (25 mg/kg). Fixed material in 10 % neutral formalin, dehydrated in increasing concentrations of ethanol (50˚, 70˚, 90˚, 100˚) and poured in paraffin blocks. Histological preparations with a thickness of 5–7 microns stained with hematoxylin and eosin were morphometrically studied to determine the relative number of cellular elements (small, medium and large lymphocytes, lymphoblasts, plasmocytes) of structural components of the iliac lymph nodes of white male rats at prolonged exposure of opioidnalbuphine and 1 week after its cancellation (Table 2, 3, Fig. 1).

4. Results

The dynamics of changes in the relative number of lymphoid cells were studied – small, medium and large lymphocytes, lymphoblasts, plasmocytes in the cloak zone and the embryonic center of the secondary lymphoid nodes and brain stretches of the lymph nodes of the white rats – males of reproductive age in normal, in the dynamics of six weeks under an influence of the nalbuphine and one week after its cancellation (Table 2, 3, Fig. 1).

It has been established that in 1–2 weeks of the introduction of nalbuphine changes of the relative number of lymphoid cells in the cloak zone and the embryonic center of the secondary lymphoid nodes and brain strands of the lymph nodes, changes in the cytoarchitectonics of the structural components of the lymph nodes were increasing during the six-week administration of nalbuphine and their cellular composition is not restored, even a week after the drug is cancelled (Table 2, 3, Fig. 2–6).

5. Discussion

The study showed that in normal (intact animals), the germinal centers of the secondary lymphoid nodes of the iliac lymph nodes of white rats-males of reproductive age are predominantly medium lymphocytes and lymphoblasts, and their cloak zone is small lymphocytes (Table 2). There are many plasmocytes in the brain lobes, and middle lymphocytes are also prevalent (Table 3).

At short-term action (within one and two weeks), the reactive changes in the cellular composition of the structural components of the iliac lymph nodes were noted on the body of the experimental animals of nalbuphine. Already after 1 week of experiment in the embryonic centers of secondary lymphoid nodes, the relative number of lymphoblasts (p<0.001) from 8.53 % (intact animals) to 10.22 % is significantly increased. This indicator increased throughout the experiment with a maximum after 4 weeks of nalbuphine action at 7.26 %. Then the amount of lymphoblasts decreases somewhat until the end of the experimental study, but even after 1 week after the cancellation of nalbuphine, the relative number of these cells is significantly higher by 5.77 % compared to intact animals. The relative number of small lymphocytes decreases accordingly, after 4 weeks they are the least – 17.7 %, at 27.93 % in animals of the intact group. The relative number of middle lymphocytes is almost unchanged (Table 2).

In the cloak zone of lymphoid nodules of the iliac lymph nodes of intact animals, small lymphocytes prevail – 69.47 %. Throughout the experiment, the number of small lymphocytes slightly changes, in contrast to large lymphocytes, which in the cloak zone of intact animals is only 2.69 %, but after 4 weeks of action of nalbuphine their number maximally increases to 4.15 %. Subsequently, the number of large lymphocytes is gradually decreasing, but even after 1 week after the cancellation of administration of nalbuphine, this indicator does not normalize, remaining significantly (p<0.001) increased and is 3.37 % (Table 2).

Small and medium lymphocytes predominate in brain stretches, the relative number of the latter during the experiment almost does not change (Table 3). Plasmocytes in this structure of the lymph nodes of intact animals are the most – 19.41 %. Already after 1 week of action of nalbuphine, the amount of plasmocytes increased to 22.34 %. Subsequent daily administration of nalbuphine leads to their maximum increase – 29.42 % after 4 weeks of the experiment. Subsequently, the amount of plasmocytes is somewhat reduced, but even one week after discontinuation of the
drug, this indicator is significantly (p<0.001) higher compared to intact animals and is 26.98 % (Table 3, Fig. 4). Also, in the brain strains the relative number of large lymphocytes is significantly increased: after 1 week of the experiment, the relative number of them increases by 2.37 %. Subsequently, the number of these cells increases with a maximum of 4 weeks of experiment up to 9.86 %. Then the number of large lymphocytes decreases somewhat, but even after 1 week after the abolition of nalbuphine, this figure is greater by 6.52 % compared with intact animals (Table 3). The relative number of small lymphocytes in brain strains under the influence of nalbuphine decreases: after one week of action of the drug – by 7.19 %, and after 4 weeks, these cells are the least as much as 21.1 %. Subsequently, the number of small lymphocytes increases slightly, but after 6 weeks of experiment they are only 10.56 %, and a week after the discontinuation of the drug – 12.52±0.41 at 28.78 % in animals of intact group (Table 3).

Comparing the results of the study with the primary lymphoid organ – thymus – where the long-term administration (six weeks) nalbuphine reduces to a slight increase in the density of lymphocytes [21], an increase in the number of lymphoblasts in the embryonic centers and plasmocytes in the brain strands of the lymph nodes suggests the compensatory and adaptive response of this organ to the action of nalbuphine.

6. Conclusions

Long-term six-week administration of nalbuphine causes reactive changes in the cellular composition of structural components of the iliac lymph nodes:

1) in the cloak zone of the secondary lymphoid nodes, the relative number of large lymphocytes is increased to 3.84 % (p<0.001); the relative number of secondary lymphocytes is reduced by 3.71 %; the relative number of small lymphocytes does not change substantially;

2) in the embryonic center, the relative number of lymphoblasts increases by 6.45 %, and the relative number of small lymphocytes decreases by 8.38 %; the relative number of middle lymphocytes varies slightly;

3) in the brains of the cerebral substance significantly increases the relative amount of plasmocytes – by 8.55 %; the relative number of large lymphocytes increases 3.4 times – from 2.67 % to 9.23 %, and small lymphocytes – decreases 2.7 times and makes 10.56 % in compare to 28.78 % in intact animals.

One week after the discontinuation of nalbuphine, the relative number of cells of the lymphoid series of structural components of the iliac lymph nodes did not change in comparison with the previous group of experimental animals and did not normalize.
